ABSTRACT

Purpose: *Rapid productisation (RP) is a new concept originating from practical challenges. RP is a process of quickly supplementing a company's product or service offering to meet unexpected customer needs. The objective of this study is to describe how an RP is used and experienced in small- and medium-sized companies (SMEs) and how the use of RP is justified in SMEs located in North America.*

Methodology: *This holistic multiple case study opens the RP concept by clarification of business case objectives set to start RP, analysis of RP challenges, and description of business justifications used for RP in the case of SMEs.*

Findings: *This study provides an introduction to the RP practises of the case companies and describes the main objectives for RP, the key challenges faced, and a deeper analysis of the business justifications used for RP. As a rule of thumb, RP is justified if it creates new business.*

Research limitations: *RP is a new concept and is not widely used. This was a clear challenge during the study. The interviewees mainly viewed RP as a more rapid way to execute the normal productisation process, resulting in time savings.*

Practical implications: *This multiple case functions as a benchmark for SME managers, intermediaries, and researchers. Our findings provide support for the managers of SMEs considering RP as one option in revenue making.*

Originality: *RP is a new concept originating from practical challenges and requires closer attention from the academic community. The academic community can provide fresh perspectives to new product development.*

Classification: *Case study*

Keywords: Rapid productisation, justification, business case, decision making, small-and medium-sized enterprises.

INTRODUCTION

Product development can be defined as the transformation of a market opportunity into a product available for sale (Krishnan and Ulrich, 2001). This is often considered as a long process with multiple checkpoints (e.g. Cooper, 2001). Based on an extensive literature review, Krishnan and Ulrich (2001) organised product development decisions into two broad categories: (1) decisions within a development project (including concept development, supply chain design, product design, and production ramp-up and launch) and (2) decisions in setting up a development project (including product strategy and planning, product development organisation, and project management). These categories of decisions are applicable to rapid productisation (RP); however, time is a critical factor in RP, and many of the methods used for decision making in the traditional product development process do not apply or need to be simplified. This study addresses decision making in setting up a development project. In particular, we focus on decisions related to business justifications of RP in small- and medium -sized companies (SMEs).

SMEs are often associated with a country's higher economic growth (Reynolds, 1997; Robson and Bennett, 2000). Beck et al. (2005) studied the relationship between the size of the SME sector and economic growth in 45 countries. They found that the share of SME employment in total manufacturing employment is associated with a higher rate of gross domestic product (GDP) per capita growth. Ayyagari et al. (2007) analysed the relationship between the relative size of the SME sector to total employment in manufacturing and GDP across 76 countries. By presenting comprehensive statistics utilising a cut-off of 250 employees, they showed that on average in these countries, the SMEs' contribution to the labour force constitutes 54% of the economy. The impact of SMEs on employment is therefore globally significant.

On one hand, SMEs are an important and integral part of every country's economy, the fastest growing sector of many economies, more flexible and adaptable in terms of structure, and having a faster speed of response than larger organizations. (Tagliavini *et al.*, 2001). In particular, the existence of a large SME sector does not directly cause economic growth but should be considered as one characteristic of a successful economy. On the other hand, SMEs typically have fewer financial resources, lower technical expertise, and more limited management skills than large companies (Blili and Raymond, 1993). These limitations affect decision making related to product development and productisation in the broader sense.

The term *small- and medium-sized enterprise* varies in meaning depending on context. In the US context, for example, the meaning of SME depends on the industry. In some industries, an SME is a company having less than 500 employees. In Europe, the SME is defined as a company having less than 250 employees. This variance needs to be taken into account when analysing SME-related literature. Ayyagari et al. (2007) covered this topic in a globally focused statistical study on SMEs:

The term SME covers a wide range of definitions and measures, varying from country to country and varying between sources reporting SME statistics. Some of the commonly used criteria are the number of employees, total net assets, sales, and investment level. However, the most common basis for definition is employment, and here again, there is variation in defining the upper and lower size limit of an SME.

Despite this variance a large number of sources define an SME to have a cut-off of 250 employees (Ayyagari *et al.*, 2007 p. 416).

In our study, we use the European definition. Within the SME category, the European Union defines medium-sized firms as having 50–249 employees, small firms as having 10–49 employees, and micro-firms as having 1–9 employees (Storey, 2003).

Innovation plays a key role in the long-term success for many companies. Customer-oriented companies are constantly challenged by the markets to keep their offering timely and responsive to the customer needs (Alam, 2002). Respectively, new service and new product development have been widely studied disciplines in academic research during the last three decades (Johne and Storey, 1998; Trott, 2002).

In many businesses the final offering is agreed in sales negotiations with the customer. Usually the product is created with a sales configuration tool or is bundled from a predefined set of components (Hvam *et al.*, 2008). Obviously a sales negotiation can lead to a situation where the customer's demands cannot be fulfilled. This usually ends the sales negotiations and the customer leaves without a deal. According to Jaakkola (2011), RP refers to those practices necessary to rapidly generate a manageable and exchangeable service offering. Little research has been carried out in the rapid response to customer requirements during the sales contact by complementing or altering the offering. Many managers and practitioners in SMEs have indicated that this kind of “rapid productisation” is a common but informal and disorganized process in practice. In addition, better management of the process would be beneficial.

Building a proper business case is key to successful decision making related to RP. Multiple methods are offered for the analysis of the business case in traditional product development; however, many of the proposed tools are too complex to be effectively used in a sales situation where decision making needs to be fast. Kinnunen *et al.* (2011) stated that a business case is for analysing ideas that come through a company's new product development (NPD) process to commit NPD resources to the right projects. The actions for building the traditional business case often include analysis of user needs, competitive analysis, market analysis, technical assessment, concept testing, financial/business analysis, and action plans (Cooper, 2001). Reviewing the details of user needs and analysis (including, e.g., in-depth market research) would take too much time in the sales negotiations and in the time frame available for RP, which requires more flexible and agile methods for business analysis. Moreover, a proper business case to justify an investment should include a business and economic rationale for the investment, a definition of the investment and its feasibility, a financial model quantifying and valuing the benefits and costs of the investment, and a plan for delivering business and financial value (BCP, 2006). It is not clear how these goals can be met in the sales situation as is often necessary for RP.

The aim of this study is to define business justifications for RP and to provide practical guidelines for managers of small business. The research questions of this study are as follows:

RQ1: *What are the business case objectives to start RP?*

RQ2: *What are the RP challenges of companies?*

RQ3: *What are the justifications for RP?*

The concept for productisation used in this study has been aligned from the case companies and provides a frame for analysis. Cases are described in detail using a framework for structuring empirical data. Our research questions evolved from the practical challenges faced by both the case company and the industry in general and are considered to be relevant for any organization interested in RP.

METHODS

This retrospective multiple case study uses a holistic research strategy (Saunders *et al.*, 2007; Yin, 2003). We divided the research process into three phases: case study design, single-case data collection and analysis, and analysis and cross-case analysis (Figure 1).

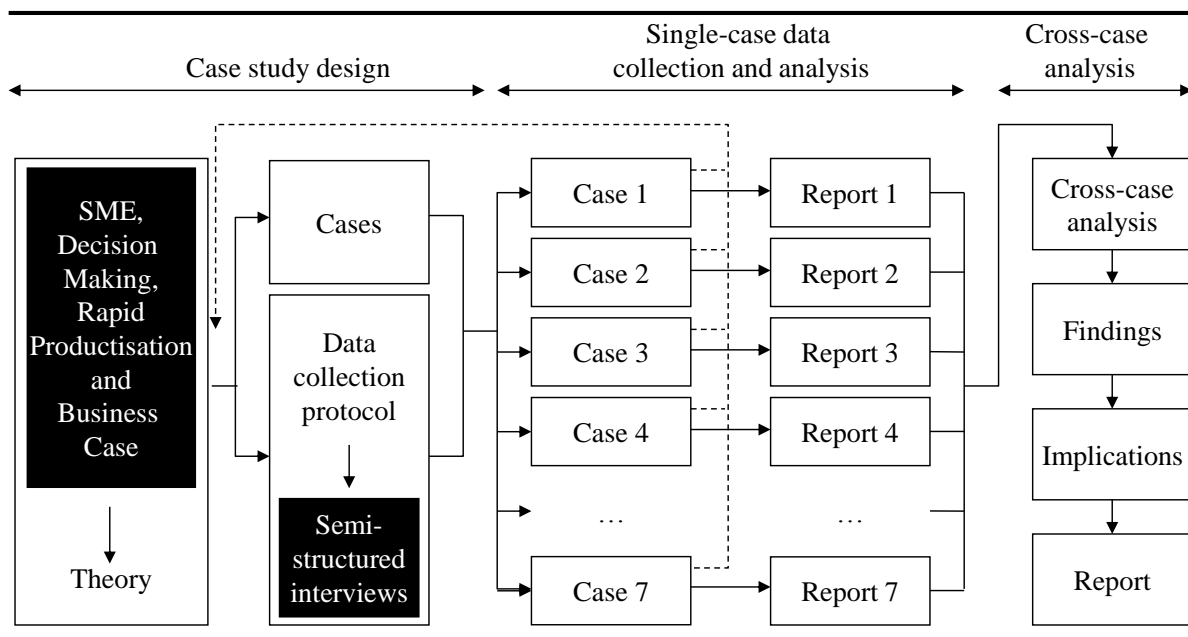

Figure 1. The research process

Qualitative research refers to any type of research that produces findings that are not results of statistical or other means of quantification (Corbin and Strauss, 2007). However, multiple data collection techniques can be employed in case studies and are likely to be used in combination with one another (Saunders *et al.*, 2007, p. 139). Moreover, both qualitative and quantitative evidence can be shown in a case study (Yin, 2003); in fact, Yin (2003) encouraged using both techniques. In line with Yin's (2003) guidelines, we collected a combination of qualitative and quantitative evidence, with the main focus on qualitative analysis. At the data collection phase, qualitative techniques may include focus groups, individual depth interviews, and case studies (Cooper and Schindler, 2010). During analyses, the qualitative researcher often uses the content analysis of written or recorded materials. Qualitative research aims at providing an in-depth understanding about the situation in hand (Cooper and Schindler, 2010).

The data was drawn from semi-structured interviews designed to gather information about the upstream supply chain in rapid productisation in US industries. Interviews were constructed to allow the interviewees to explain and clarify the case and topics as entities. Interviews

were conducted in seven heterogeneous companies to obtain a wider view on the subject studied (Table 1). These companies were able to provide comprehensive study material and the extent of the phenomenon of RP.

The companies' advanced practices and advanced product development processes can be used to compare other participating companies. The topics that were company specific are not reported. Altogether, the study included 11 interviews (Table 2). The interviewed industry experts were carefully selected based on their professional background and expertise. The selected participants hold positions related to productisation. Their experience and current interest ensured high motivation and relevant knowledge about the topics discussed. The questionnaire was sent early enough to enable the interviewees to review it in advance. The interviews were recorded and transcribed and lasted up to 2 hours each.

NVivo®, QSR International Pty Ltd, Australia made software was used in organizing and analysing the interview content and for criteria categorization. For each company, we conducted a within-case analysis and classified the cases according to the following categories: RP, business case for RP, and RP challenges. Company characteristics are presented in Table 1.

Table 1. Case company characteristics

Case	No. of interviews	Role of the interviewee	Area of business
A	1	CEO	Electronics manufacturing
B	1	CEO	Software solutions and equipment manufacturing
C	1	CEO	Telecommunication
D	2	CEO and Director of Marketing	Software solutions and consumer goods
E	2	CEO and Manager of Product Development	Software solutions
F	2	CEO and President of Sales/Marketing	Software solutions
G	2	CEO and Bio Technology Consultant	Biotechnology

RESULTS

The study was carried out in a multiple case study that incorporated electronics manufacturing to biotechnology SME companies located in North America. The companies are referred to as A, B, C, D, E, F, and G (Table 2).

Table 2. Case company information

Case	Founded	No. of employees	Current total sales (\$ Milj.)	Current value of assets (\$ Milj.)
A	1971	37	12.00	10.00
B	1995	30	5.70	2.50
C	1999	25	sensitive	sensitive
D	2009	18	2.00	6.00
E	2003	15	0.50	0.39
F	2009	11	1.30	2.90
G	2009	7	0.10	4.50

Rapid Productisation

Company A, an electronics manufacturing company located in Washington, aims to minimise interference with the standard product by using the same housing, plugs, or connectors. The benefit is that the company can optimise its ability to buy parts in volume, although perhaps at a lower volume, based on the business case. The project manager plays a key role during the RP process and is very involved throughout the process rather than a commodity salesperson that looks for a customer, takes an order, and moves on. RP also requires a more involved sales and purchase integration process. The drawback is the company needs to have more people internally, which would then change its structure from being ‘lean and mean’.

Company B is a software solutions and equipment manufacturer located in California. A need for RP with a request to change the product roadmap pops up regularly when the research and development (R&D) section is working on a new product development case. One reason why there are so many new requirements coming from customers is that company B is in a relatively early developmental stage. The product roadmap released to the market may have a reduced functional subset and does not fully satisfy customers, which is why customers return to the company for a specific derivation. The company needs to make a decision whether to rapidly develop and productise a solution for the customer or put it into a proposal for future development. Company B tries to avoid developing a solution for only one customer. RP requires an extra effort because usually the solution needs to fit into the long-term strategy for the company. By doing RP lower level of investment might reduce the development cost to that of NPD, but might not necessarily be less.

Company C, a telecommunications company located in Maryland, has been incorporating RP for several years, and this causes challenges in the sales situation. Company C’s business is as a small-volume, highly customised industry. RP enables the company to be predictable and to give the customer proper feedback. Historically, if the customer was willing to buy, the company was willing to invent it, and this is how the company developed its product line. Currently the company’s product line offers better conditions, and the company has done sufficient development to ensure the product line can satisfy most customers immediately. The company is now shifting towards stronger prioritisation in product development and are examining whether there are other sales opportunities.

Company D is a software solutions and consumer goods company located in California. Sales face a need for RP basically every week. The situation is challenging to sales, and employees

probably do not manage it as well as they should. First, many customers ask for the same things. In these situations the sales group is able to provide a response because the company is familiar with the question. From the interview:

“I think if you do your work upfront and you need to make self-question does it fit into our business model. Are the bulk of the customers wanting it or willing to commit to buying it? And then, what’s the longevity of the product? Is it a one-time product or is it something that can be offered over and over and over through time? You reduce a lot of your challenges and your risks because you’ve done your work upfront, which doesn’t take that much time, in an effort to better ensure success”.

However, for a new request where RP is required, they really cannot give a reliable response for at least three reasons: in a typical sales–engineering relationship, sales tend to overpromise and engineering subsequently under delivers. It endangers the business when sales overpromise deadlines and promise certain customers that they can skip a line. From a sales’ perspective, it is all about understanding the customer’s thoughts and the company’s business. Usually the sales person just goes to the marketing team and asks for these new features. In the case where the feature is necessary, it gets advanced on a schedule and other things are moved down; however, if it is a feature that is nice but not essential, it is placed on the wish list.

Company E is a software solutions company located in California. The company has not had a single customer that is has paid to build one particular product. Instead they have multiple customers who are interested in similar things. If RP is used for one customer, it requires customer integration on the company’s sales cycle. Even when produced initially for one customer, a product should be useable by other customers. It is typical that a customer is interested in the standard product but wants to see a proof of concept application in the demo that requires the company to build a fast add-on. To do this requires a live demonstration in a configuration using data the customer is interested in. The decision to do or not to do RP depends on the amount of work needed. Sales have an important role and have to define and describe what it is the customer is asking for. From the interview:

“Because sales is always spinning around different crazy stuff development has to stay focused and disciplined to get things done, otherwise they’d be moving around and they’d never finish”.

It is important that a definition of scope is very clear in the case of RP. In the business culture, the sales staff have to be sure they are dealing with people that have the authority to make the decisions. It is important that a customer knows what they want. When the company has a good team to work with and the team has a good dialogue with the customer, it is very constructive, making it safe for the company to do RP.

Company F, a software solutions company located in California, historically did more RP. Its situation has changed, and currently the company gets more requests for its products, which are equal to market standards and getting more advanced. When the company first started operating, it often needed to provide RP to win clients, but now RP is used more as an enhancement. The company seeks to increase agility just by constantly adding features. A basic software release cycle is 1 to 2 weeks, and the company has a 60- to 90-day release cycle once a year to develop effort-intensive functionality. An ability to balance the work load of development is crucial. It is not good for business if all on-going development needs

to stop to address an RP; this happened once and everything else was delayed by 6 weeks. Company F is going to change that in the future. The company's target is to save part of the business for RP and the rest of the business for its core direction.

Company G, a biotechnology company located in California, was interviewed at the time when RP was needed. The company has the ability to deviate from their platform portfolio, and this has been done several times. From the company's perspective, it is important to meet the needs of customers and it is something the company is able to do. From the interview regarding how to be agile:

"You know nothing big, fancy, no 10,000 dollar market research studies, just an airplane trip to Atlanta to meet people over a cup of coffee."

Making fast decisions and quickly developing a new business plan are things that small companies can usually do better than large companies. A request from a customer for an RP in sales is a common topic and in many cases RP can be done. The company has received more and more product portfolio-related questions "...can you have that or this...", and this has been a recurring event over the past 2 years. It is a clear indication for RP and highlights the missing part in a company's normal offering. The sales situation is all about listening to a customer and then reprioritising the requests. In a small company like G, one of the key management responsibilities is to constantly evaluate how much effort an RP requires versus other development—balancing on-going work and at the same time maintaining opportunities to have flexibility with RP. Management needs to ensure that development is not stuck and prioritisation is constantly being re-evaluated.

Business Case Objectives for Rapid Productisation

In *Company A*, the basic business purpose is to make a profit. The company makes money by making products and thus do not sell engineering time. Business justifications for RP are to build a product that will sell and either make a large profit or potentially develop a new market. The justification for building a new design is to be a stepping stone to something else. If the customer preferences can be met, the company can justify a marginal fiscal performance on their first orders because they assume it will attract future customers, which could then place the company in a new market or give the company something new to develop in the long term. Company A is always looking for something new.

Company B, as an early stage company, views the ability of a customer to pay to enhance their product in a way that the company would eventually do, as optimum. A core business case for RP is having a better product that will grow the company in the future. This is an incredibly strong driver for doing RP even if it is disruptive to the organisation in the short term. When a customer inserts itself into the RP process by having a short-term need that drives revenue, the company tends to be responsive because from the company's perspective, R&D will be free. This is important. At present, it not only helps Company B to accelerate revenue but also helps accelerate product development, which is a win-win-win situation—a win for sales, for product development, and for the end customer who gets something that is needed.

In *Company C*, the Chief Financial Officer would prefer a world where there are always customer requirements, customer orders, and the engineer is only working on something that

the customer is willing to pay for. In the early years of Company C, this was not the case. The main reason to start RP is a business case that will guarantee enough sales, feasible technology to justify an engineering effort, and appropriate prioritisation. RP is a qualitative weighing of nonrecurring engineering effort versus potential sales.

In *Company D*, RP should fit a business strategy. Company service builds on the affinity of their buying network. The network can be seen as a scalable layer that accelerates business. RP has to meet financial goals and be profitable. Simply, the company needs to be able to make a profit from RP. The business case for RP will be met when a new product incrementally increases sales and not just splits sales.

In *Company E*, the business cases to start RP are: a reasonable scope, no technical risk to build a product, resources will be available, doable schedule, and the promise given to the customer can be met. Company E is small, and one of the problems with RP is the need to maximise an opportunity cost. When the work has been done, it is essential to leverage effort into a new product line or complement the product line the company is already investing in. To keep it simple, if there is a customer willing to purchase the product, the best business case the company can get is being able to sell the product.

There are two business cases for RP in *Company F*. The first is what the revenue for a client is and this has to be more than \$10,000 per year. The second is the question, is it a solution that the company can apply to all their other clients as well to make a greater profit? The main target from RP is to get something for a product portfolio and something that the company can universally use for all their clients. Otherwise, the company tells customers they need to find a third-party developer. The client has to have available resources and must be dedicated to a successful program once the company has built the product.

Company G has no formal processes because the company and its market are relative small. The company uses unformed processes and relies on market forecasts. The company likes to keep things simple. The business case for RP is a positive return on investment. The business case to start RP requires that there are enough sales, feasible technology to justify an engineering effort, and it is prioritised appropriately. Small companies need their revenue sooner rather than later. The company has to survive on RP development because it generally does not have three or four projects that are on-going.

Rapid Productisation Challenges

When using RP, *Company A* tries to find a product that fits a wider market. RP cannot be used to build a totally new product. As an example, total product development time for a tactical communications product ranges from 12 months to 14 months. One version of the product range is the way the company can make the best profit. If there is a need to make 14 versions of the product and to sell it to 14 different clients, there are risks that the package or features will not be set correctly. If use of RP requires third-party vendors, it is essential to know the person the company is going to deal with. From an interview with a purchase manager about the CEO's response to possible vendor use: *'Oh, I don't want to use that vendor because they will be a risk for us. Can't you use anybody else?'*

Company B is working on a software as a service model. They would not do RP just for revenue but want the visibility that comes with enhancing a product. Upstream supply chain management needs extra attention. From an interview:

“Upstream supply chain is typically less able to respond than we are, and they are typically less motivated to respond than we are. And that has to do with I think the whole small versus large company thing because we are typically sourcing from larger companies than ourselves”.

If a customer really wants something that is going to impact the experience of the rest of the user community, it obviously carries much more expense from development. One-off or bespoke services is different. When the company does RP, it is a disruption, which is why a product should support the customer, make it better overall, and leave no negative impact to the customer experience. Parallel RP and NDP is difficult for a relatively small company.

For *Company C* the main reasons not to do RP are mainly related to different technically feasible challenges or capacity shortage in the product line, even when the customer is willing to buy a product. One solution to solve capacity shortage is outsourcing resources. From an interview:

“...we have in fact done some of that in the past when we’re just really busy. It’s a way to add bandwidth without having to add to the payroll”.

In *Company D*, the cost of developing is prohibitive and starts to impact the company’s regular business. They have to take people off from developing and selling to do on-going projects. At the moment the company does not have enough manpower to support RP. If there are five things a customer wants facts for, three of them are ones that the company can do well. The other two customers requests will be put on the list for future development.

Company E can earn acceptable profits from RP in terms of pricing and profitability. Problems occur if the products are just one-off instead of products that the company can sell to a number of customers. RP in the company’s market place requires having a lot of employees, which is the main reason the company is not able to do many one-off products.

Company F will never build anything that only one client would own. There is also the need to have them ‘right client’ for RP. From the interview:

“Some of our clients will pick bad developers and they screw things up. And they’ll pay us to fix them”.

The client should also have existing customers available for the product.

The main limiting factor for RP in *Company G* is how to set correct priorities to manage development. From the development perspective, RP requires that everything goes smoothly. When problems occur, these have to be solved fast. RP is not a typical research project.

ANALYSIS AND DISCUSSION

As a result of this study, the justification for RP in the case companies was described based on the interview data. The interviewed case companies commonly ended up either spinning off a new product or enhancing the existing product based on a customer’s needs. When there is the need to modify products to meet only one customer’s requirements, there has to be a

revenue opportunity, which requires that the product functionality later becomes a part of the product/service portfolio available for other customers. Portfolio management practises should be in use to support RP. A formal process for reviewing and handling customer's requests received from RP is essential. A summary of RP is presented in Table 3.

Table 3. Summary of rapid productisation

Role of sales (salesperson) is critical
Way to resolve situation when current product roadmap does not satisfy customer
Challenge situation in sales and important that the customers know what they want
Way to win clients and meet needs of customers
Sales and R&D integration
Used more in company's early stage phase
Target to have a portfolio-wide solution not a single customer
Could be needed basically every day
Requires ability to make fast decisions and prioritisation re-evaluation
Quick development of new business plan
Right balance between RP, core business, and effort

As an answer to RQ1, before starting RP a company needs to do more market research and not just react to something that sounds good. Before creating something, a company wants to be able to leverage it across the entire platform. According to interviewees, the basic financial justification of an RP project is based on evaluated income from the project. However, situations where this is not the case were mentioned. For example, an actual feature has already been promised or the deal is somehow secure if the customer requirement can be met. One interviewee even mentioned that some projects are justified primarily based on intuitive decisions about profitability. It was also pointed out that these projects must have full support from top management. Table 4 summaries the objectives for the RP business case.

Table 4. Objectives for RP business cases

Build a sellable product to make money
Reach new markets or product segments
Core for long-term development and growth of business in near future
Accelerates product development
Prioritisation can be made without compromising the existing roadmap
Fits a business strategy and supported by management
Business opportunity upsurge for financial goals and revenue
Incrementally grows sales and not just splits sales
Promise given to the customer can be met

To address RQ2, a sudden need for RP in sales is a challenging task for sales people. It endangers the business if sales overpromise deadlines and promise certain customers that they can skip a line without better knowledge of what is needed. Challenge areas for RP from management are: 1) a relationship between sales and engineering, 2) sales not overpromises and/or overestimates requirements, and 3) engineering will not under deliver. Sales has to ensure they are dealing with people that have the authority to make the decisions. It is

important that a customer knows what he or she wants. It is best when a customer has some technical knowledge in an area under sales negotiations.

When RP is targeted to more than one customer it will require an extra effort because the solution needs to fit into the longer term strategy for the company. An essential issue for RP is that sales, development, and management know how the customer's request for the product/service fits within the objectives and scope of the company's strategy. Table 5 summaries the RP challenges of the case companies.

Table 5. Summary of rapid productisation challenges

Fit for wider markets and product portfolio compatibility
Not for totally new products or use of new technology
Prioritisation between RP and NPD
One-off products could increase unnecessary product variety
Upstream supply chain and third-party vendor management

To address RQ3, the business is not feasible if all on-going development needs to stop for tackling RP. This happened with one case company and other work was delayed for 6 weeks. The company is going to change this in the future. The company target will be save part of the business for RP and the rest of the business for the core direction. Are the financial benefits so big that the project is worth doing even if partner companies must be used? Is the project a possible entry to a new customer segment or market area or even a new single customer that is big enough? One key point to address is also whether the project would help the company in differentiation from competitors. The company should also be able to test the solutions early on. RP is justified if it creates new business. The analysis is always made beforehand based on the business justifications and resources the company has available. Justifications for RP are presented in Table 6.

Table 6. Justifications for rapid productisation

A reasonable scope and line with company strategy
No technical risk to build a product or service
Resources and needed knowledge are available
Doable schedule and promise given to the customer can be kept
Work is added with equal revenue
As a company grows and matures, each new sale is not as important
A new product will incrementally grow sales and not just split sales

CONCLUSIONS

It is essential when using RP that the RP process is dynamic and all advantages of existing frameworks are fully integrated. Responsibilities between sales and R&D need to be clear. After starting RP, conversations between sales and R&D need to be smooth and objective. In the company everyone should be on the same page. Well-executed portfolio management in cooperation with RP is one way to minimise unnecessary growth of product variety.

Use of third-party vendors to support a resource shortage need to carefully examined because vendors could be less motivated to respond and it might cause challenges in a later phase. Being able to keep a promise given to customers is a must for RP. Company has the ability to lose the trust of a customer only once.

Using RP does not mean that product development costs are automatically small. Cost of development might be the same as NPD and not necessarily be less. RP requires sufficient sales potential and should be technologically feasible. It must be able to justify the engineering effort and be able to prioritise appropriately. RP is a qualitative weighing of nonrecurring engineering effort versus potential sales.

Managerial implications

One proposal for how management could solve the challenge in sales negotiations is to explain to sales people where the company's market is compared to the full market place. Sales should increasingly look at not just whether there is one sale but could there be several sales opportunities.

Has the company capacity to spare for the project? In small companies one of the key things management needs to do is constantly evaluate how much effort could be put to RP versus other development (i.e., NPD). Management needs to balance on-going work and at the same time maintain flexibility for RP opportunities. Management needs to ensure that development is not stuck and prioritisation is being re-evaluated.

Limitations

This study has focused on small business use of RP. Addressing some of the limitations of this study should stimulate further research. First, the number of interviewed companies is limited; a deeper analysis is needed to broadly cover the studied topic. Secondly, our study focuses on small companies. The next step would be to study what might be justifications for RP in large companies. Third, it would be interesting to examine in more depth how new companies can utilise and take advantage of RP to boost companies' early growth.
